

Studying the stellar populations in the fuzzy cores of young massive clusters

Zeinab Khorrami

P. Clark (Cardiff University), F. Vakili (Observatoire de la Cote d'Azur),
T. Lanz (Observatoire de la Cote d'Azur)

29 June 2017

Cardiff University

Young Massive clusters

Dense aggregate of newly formed stars with lots of difficulties!

- Immersed in gas/dust: High (inhomogeneous) extinction

Observations in longer wavelength

- Most of them are not close enough: their individual members probably are not resolved

High angular resolution observations

- Massive hot stars mask the faint low-mass stars.

High contrast imaging

DSS2 Blue

FoV: 23.03'

DSS2 Red

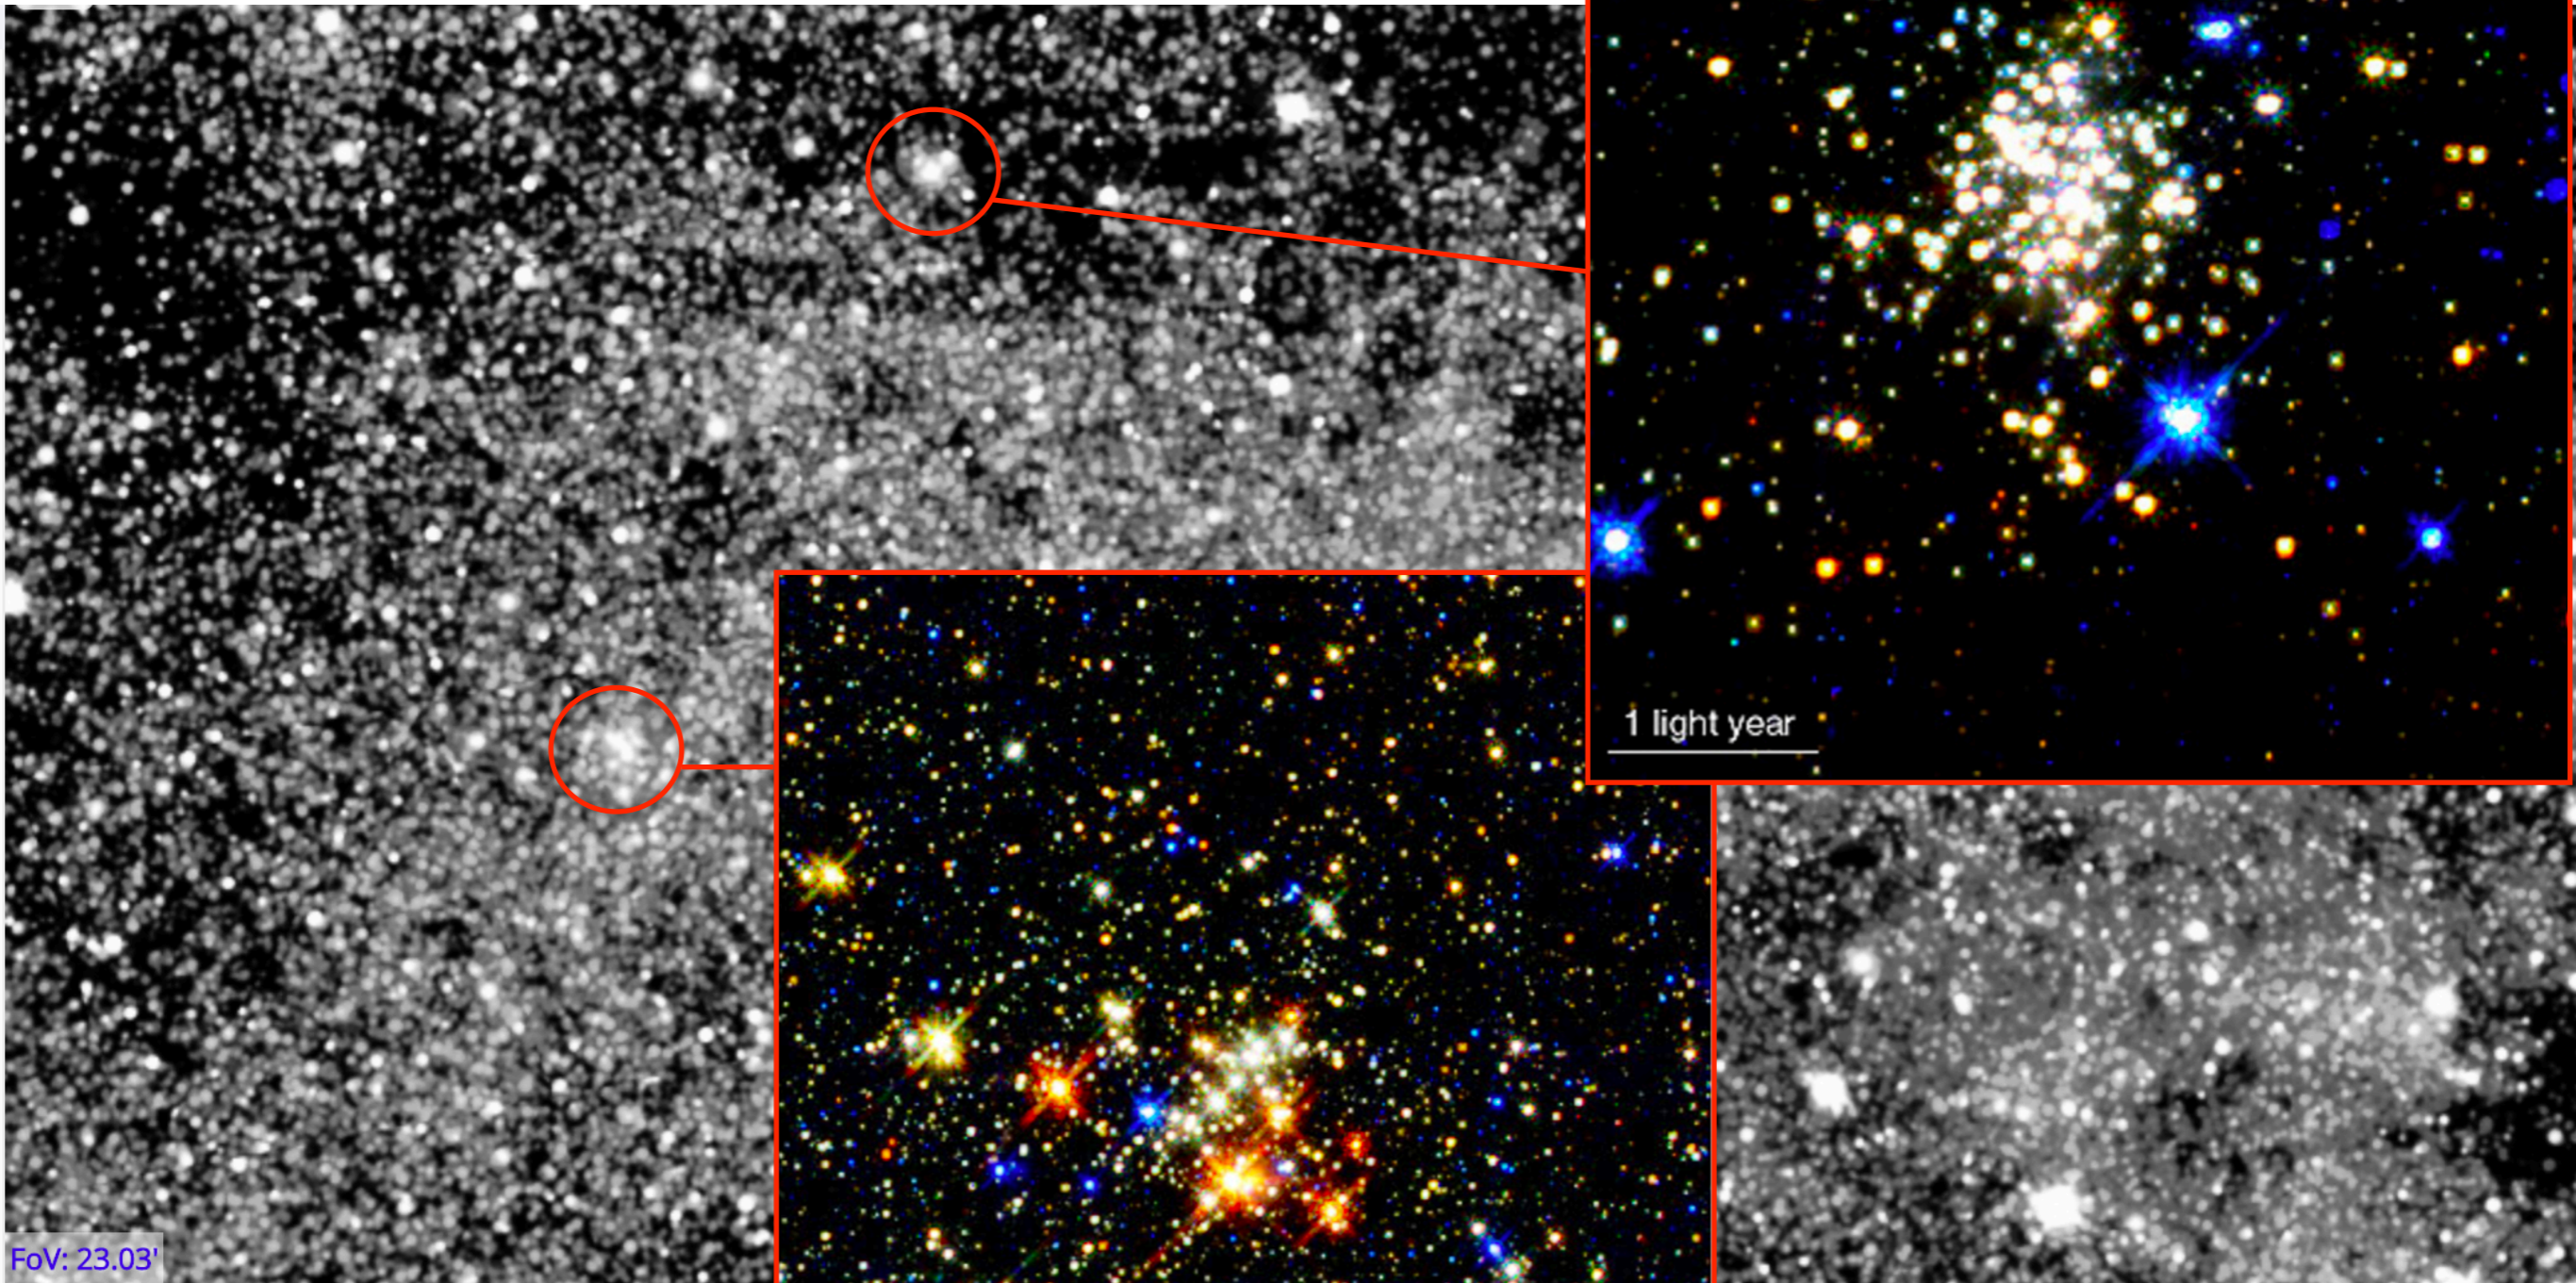

FoV: 23.03'

2MASS J,H,K

2MASS J,H,I

FoV: 23.03'

Next step ...

1. Proper evolutionary/atmosphere model
2. Estimating stellar masses, ages
3. Investigate physics of the newly formed cluster:
 - MF, density profile, Virial status, mass-segregation
 - Feeding cluster-formation simulations, gravitational-dynamical evolution
 - Filling the gap between cluster formation and evolution

Final step ...

To compare simulations with observations we should use
synthetic observations

in different distances

NGC 3603

NGC 3603

NGC 3603

$$M_{total} \sim 10^4 M_{\odot}$$

$$Age \sim 1 - 2 Myr$$

$$Dis \sim 6 - 7 Kpc$$

Constellation : Carina

NGC 3603

MF slope	condition	Reference
-0.73	$(1 - 30) M_{\odot}$	[Eisenhauer et al.1998]
-0.9	$(2.5 - 100) M_{\odot}$	[Sung & Bessell2004]
-0.5 ± 0.1	$r < 6''$	[Sung & Bessell2004]
-0.8 ± 0.2	$6'' - 12''$	[Sung & Bessell2004]
-1.2 ± 0.2	$r > 12''$	[Sung & Bessell2004]
-0.91 ± 0.15	$(0.4 - 20) M_{\odot}$	[Stolte et al.2006]
-0.31	$0 - 5''$	[Harayama et al.2008]
-0.55	$5'' - 10''$	[Harayama et al.2008]
-0.72	$10'' - 13''$	[Harayama et al.2008]
-0.75	$13'' - 30''$	[Harayama et al.2008]
-0.26	$0 - 5''$	[Pang et al.2013]
-0.55	$5'' - 10''$	[Pang et al.2013]
-0.76	$10'' - 15''$	[Pang et al.2013]

Different observations

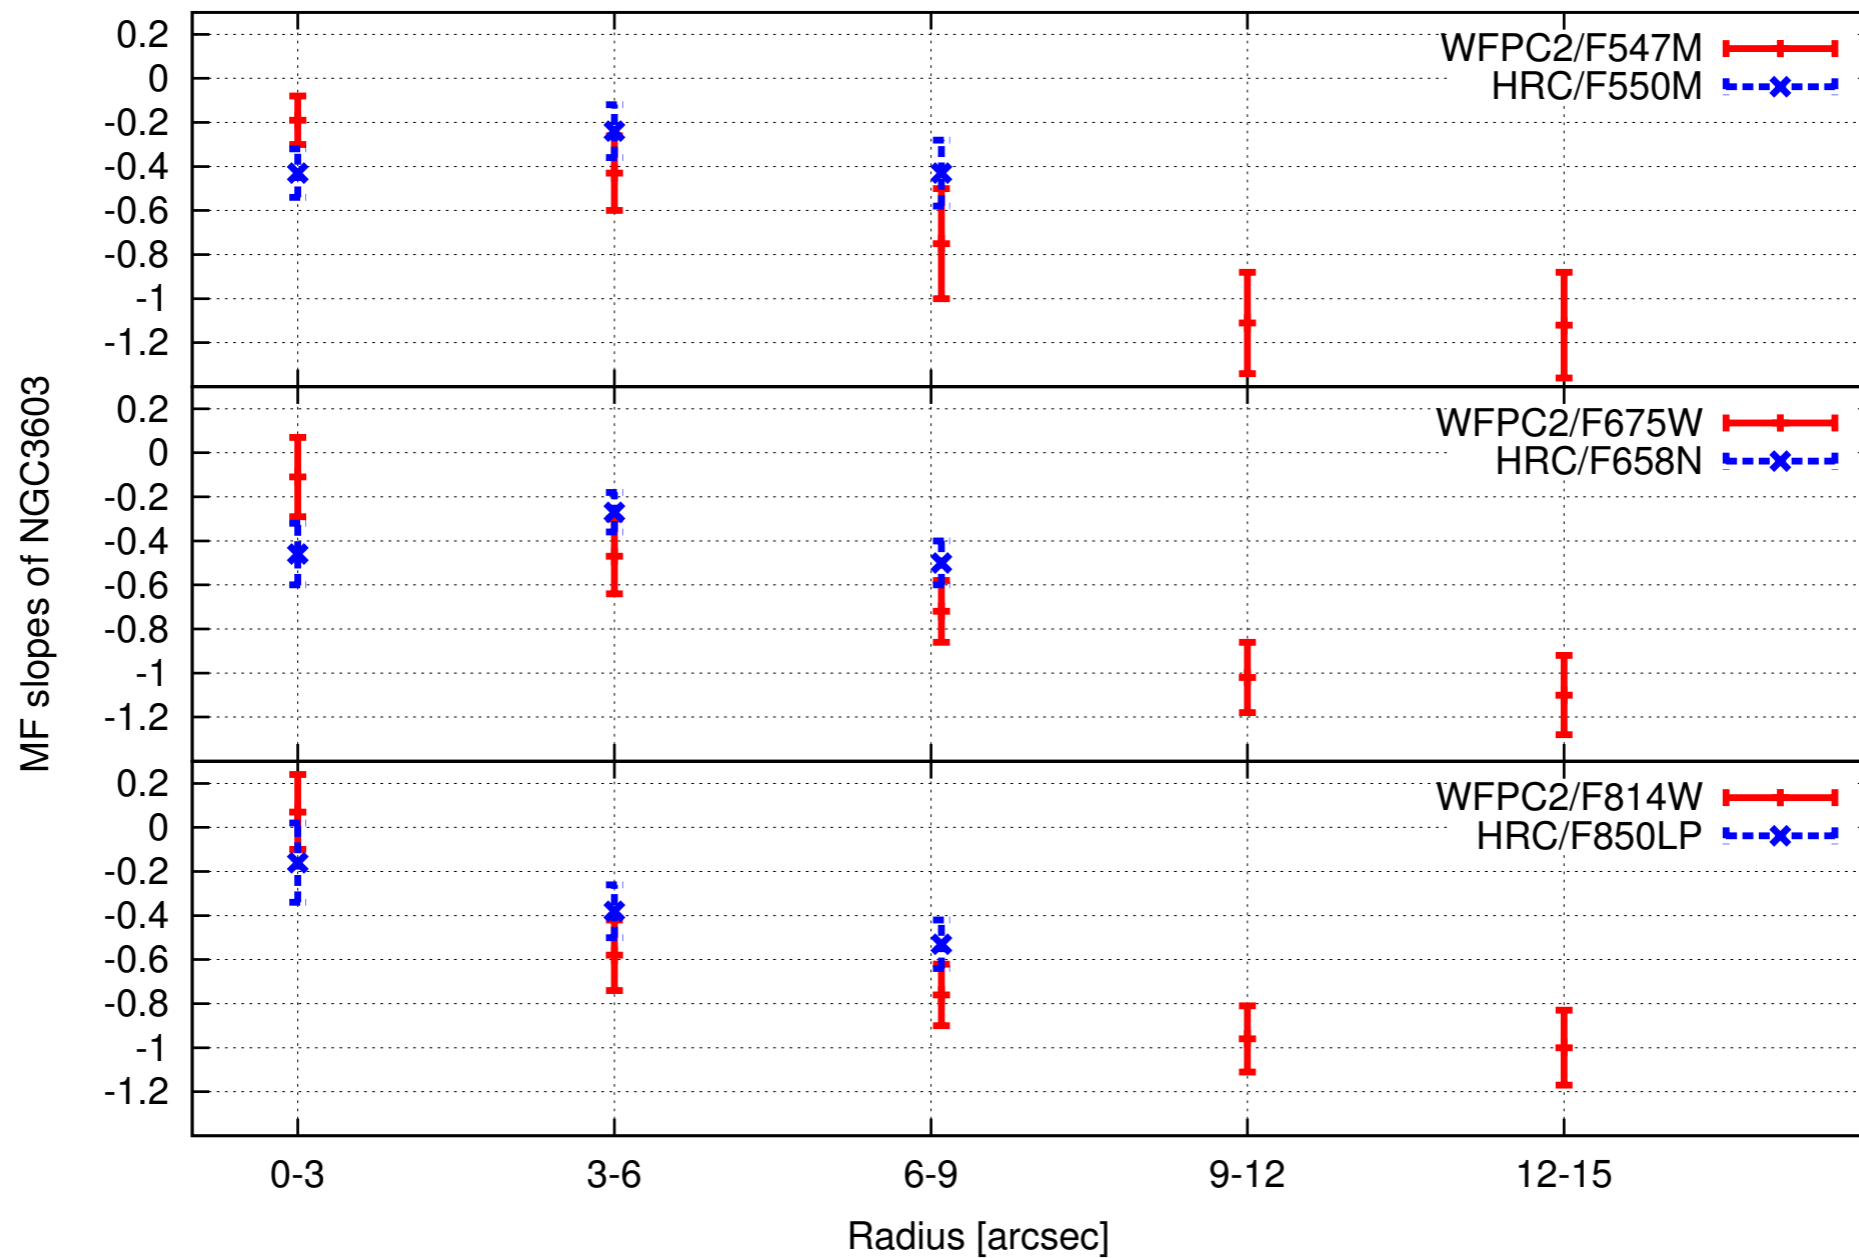

Different MF slopes

WFPC2
Filters: V,R,I
50mas/pix

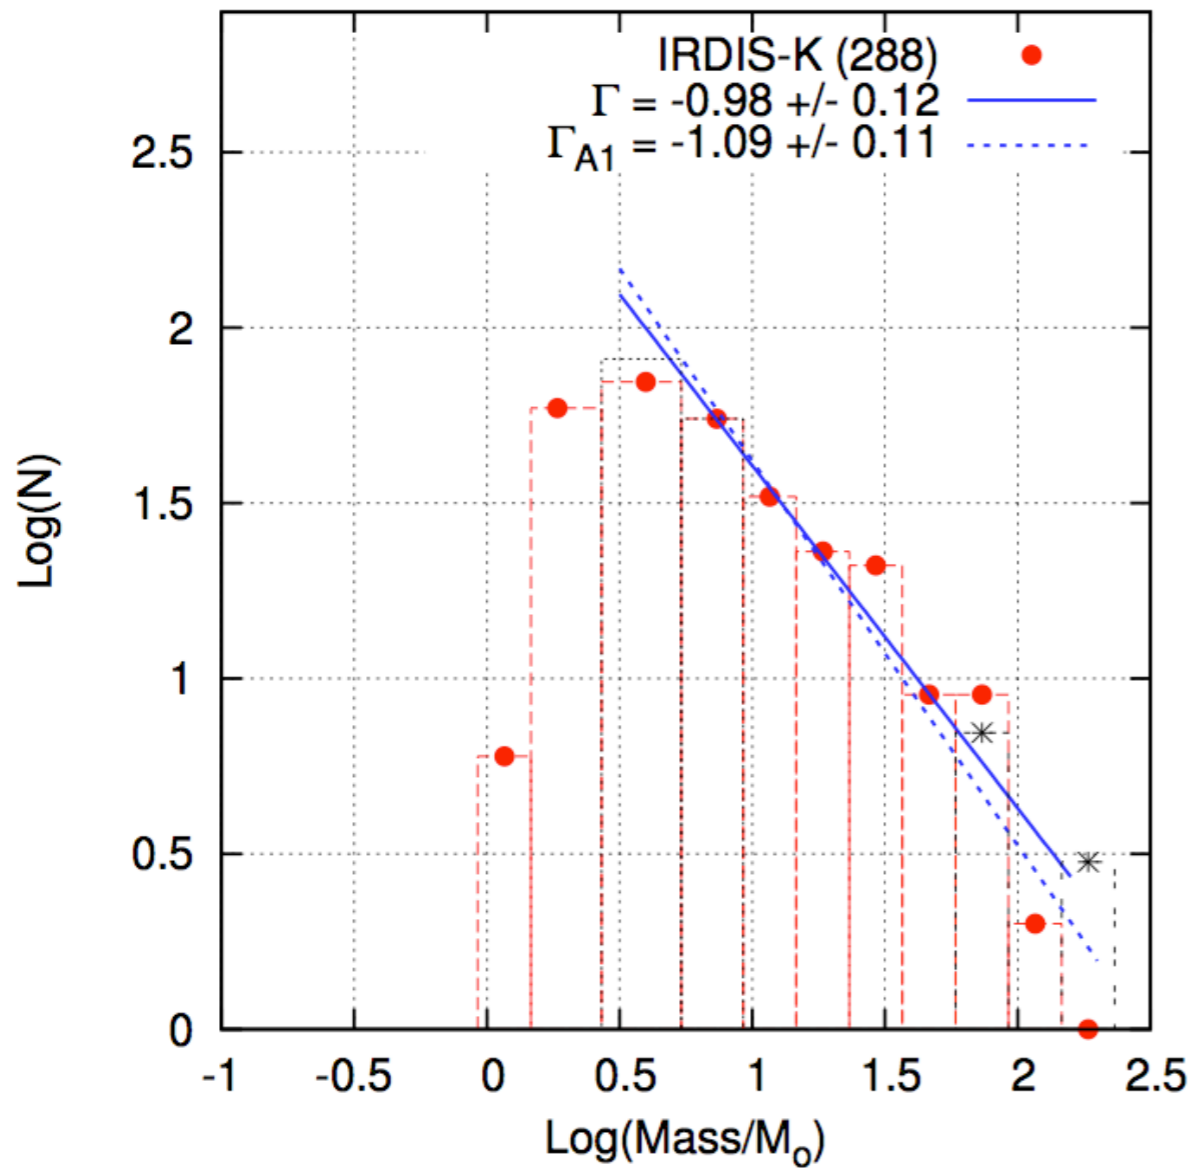

ACS/HRC
Filters: U_x,U,B,V,R,I
25mas/pix

WFPC2 shows the decreasing trend in MF slope... signature of mass-segregation BUT this is not the case for HRC data

High angular and contrast images from VLT/SPHERE

No signature of mass segregation in the core of NGC 3603:

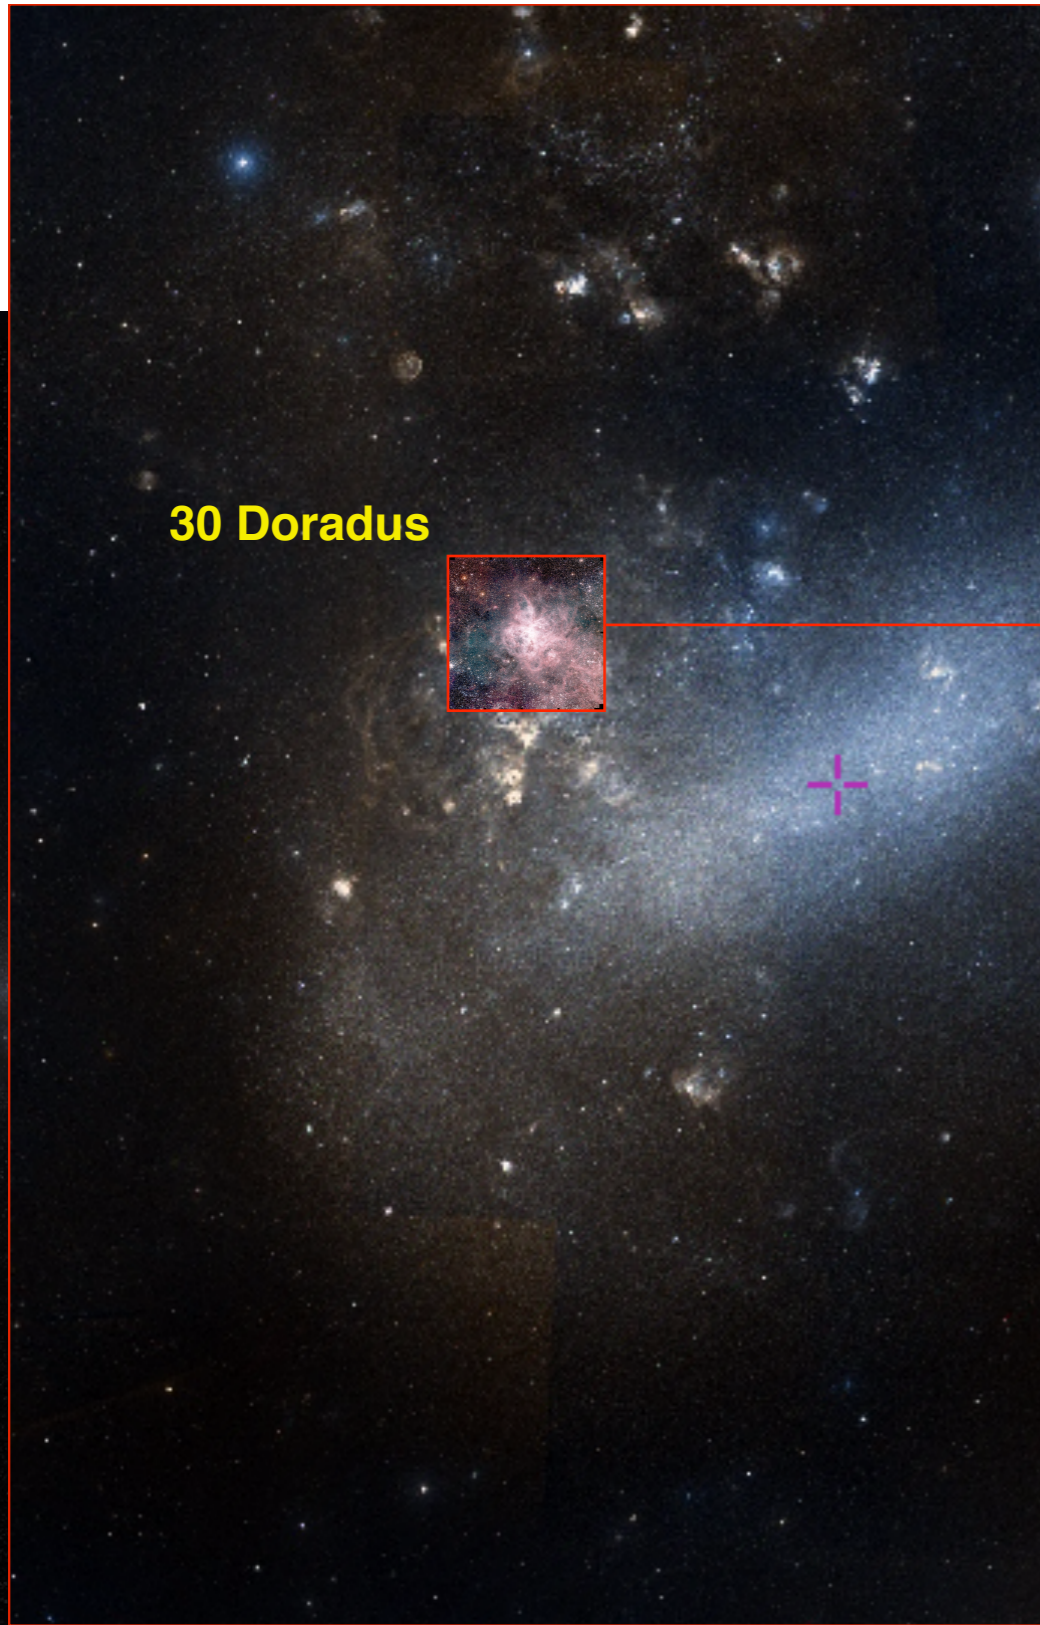

- 1) The MF slope in its very core is not flatter than the next radial bin
- 2) Both slopes are similar to the MF values found in previous works for the outer regions

[Khorrami et al., 2017, A&A, 588, id.L7]

MF at 0.6, 1 and 1.5 Myr; $N_{\text{total}} = 818$

[Khorrami et al., 2017, A&A, 602, A56]

MF is sensitive to the observations
and models

How can we simulate observations?

Make Your Synthetic Observations

Inputs:

Stars information (from N-body): 3D position and Velocity, Mass, age, metallicity

Cloud information (from SPH): 3D position, particle's mass, smoothing lengths

Observational Filter (from the list)

Imaging angular resolution AND Spectroscopic resolution

Distance of the centre of mass

FoV

R_v for extinction

Adaptive optics: seeing and SR

OB-treatment: TLUSTY model atmosphere

Velocity dispersion

Euler angles for line-of-sight

Signal/Noise ratio for the faintest star

Summary and conclusion

- MF is sensitive to the resolution of the observational instrument
 - Observers need to compare the data with different resolution
 - We always need higher angular resolution data with better contrast
- Synthetic observations are needed to compare simulations with Observations
- MST method can detect mass-segregation in the simulated data
